University of Wisconsin-Madison

Milano
18-23 November
2013
What We Covered Yesterday…

- GPU computing w/ thrust
- Parallel computing with OpenMP
  - Parallel regions
  - Work sharing
    - Parallel for
    - Parallel sections
    - Parallel tasks
  - Scheduling
  - Data scoping
Acknowledgments

- Parts of MPI material covered draws on a set of slides made available by the Irish Centre for High-End Computing (ICHEC) - [www.ichec.ie](http://www.ichec.ie)
  - These slides will contain “ICHEC” at the bottom
  - In turn, the ICHEC material was based on the MPI course developed by Rolf Rabenseifner at the High-Performance Computing-Center Stuttgart (HLRS), University of Stuttgart in collaboration with the EPCC Training and Education Centre, Edinburgh Parallel Computing Centre, University of Edinburgh

- Individual or institutions are acknowledged at the bottom of the slide, like

MPI: Textbooks, Further Reading…

- **MPI: A Message-Passing Interface Standard** (1.1, June 12, 1995)
- **MPI-2: Extensions to the Message-Passing Interface** (July 18, 1997)
- **Parallel Programming with MPI**, Peter S. Pacheco, Morgan Kaufmann Publishers, 1997 - very good introduction.
- **Parallel Programming with MPI**, Neil MacDonald, Elspeth Minty, Joel Malard, Tim Harding, Simon Brown, Mario Antonioletti. Training handbook from EPCC
Shared Memory Systems

- Memory resources are shared among processors
  - Typical scenario, on a budget: one node with four CPUs, each with 16 cores

- Relatively easy to program since there is a single unified memory space

- Two issues:
  - Scales poorly with system size due to the need for cache coherence
  - Most often, you need more memory than available on the typical multi-core node

- Example:
  - Symmetric Multi-Processors (SMP)
    - Each processor has equal access to RAM

- Traditionally, this represents the hardware setup that supports OpenMP-enabled parallel computing
Distributed Memory Systems

- Individual nodes consist of a CPU, RAM, and a network interface
  - A hard disk is typically not necessary; mass storage can be supplied using NFS

- Information is passed between nodes using the network

- No cache coherence and no need for special cache coherency hardware

- Software development: more difficult to write programs for distributed memory systems since the programmer must keep track of memory usage

- Traditionally, this represents the hardware setup that supports MPI-enabled parallel computing
Overview of Large Multiprocessor Hardware Configurations

- Larger multiprocessors
  - Shared address space
    - Symmetric shared memory (SMP)
      Examples: IBM eserver, SUN Sunfire
    - Distributed shared memory (DSM)
  - Distributed address space
    - Commodity clusters: Beowulf and others
    - Custom cluster
      - Cache coherent: ccNUMA
        SGI Origin/Altix
      - Noncache coherent: Cray T3E, X1
      - Euler
      - Uniform cluster: IBM BlueGene
        - Constellation cluster of DSMs or SMPs
          SGI Altix, ASC Purple

Euler

~ Hardware Configurations ~
Hardware Relevant in the Context of MPI
Two Components of Euler that are Important

- **CPU**: AMD Opteron 6274 Interlagos 2.2GHz
  - 16-Core Processor (four CPUs per node → 64 cores/node)
  - 8 x 2MB L2 Cache per CPU
  - 2 x 8MB L3 Cache per CPU
  - Thermal Design Power (TDP): 115W

- **HCA**: 40Gbps Mellanox Infiniband interconnect
  - Bandwidth comparable to PCIe2.0 x16 (~32Gbps), yet the latency is rather poor (~1microsecond)
  - Ends up being the bottleneck in cluster computing
The same program is launched for execution independently on a collection of cores.

- Each core executes the program.

- What differentiates processes is their rank: processes with different ranks do different things ("branching based on the process rank").
  - Very similar to GPU computing, where one thread did work based on its thread index.
The Message-Passing Model

- One starts many processes on different cores but on each core the process is spawned by launching the same program
  - Process definition [in ME759]: a program counter and address space

- Message passing enables communication among processes that have separate address spaces

- Interprocess communication typically of
  - Synchronization, followed by…
  - … movement of data from one process’s address space to another’s

- Execution paradigm embraced in MPI: Single Program Multiple Data (SPMD)
The Message-Passing Programming Paradigm

- Sequential Programming Paradigm
  - A processor may run many processes

- Message-Passing Programming Paradigm
  - Distributed memory
  - Parallel processors

communication network
Our View: A **process** is a **program** performing a task on a **processor**

Each processor/process in a message passing program runs an instance/copy of a **program**:
- Written in a conventional sequential language, e.g., C or Fortran,
- The variables of each sub-program have the same name but different locations (distributed memory) and different data!
- Communicate via special send & receive routines (**message passing**)
# A First MPI Program

```c
#include "mpi.h"
#include <iostream>

int main(int argc, char **argv) {
    int my_rank, n;
    char hostname[128];
    MPI_Init(&argc,&argv);
    MPI_Comm_rank(MPI_COMM_WORLD, &my_rank);
    MPI_Comm_size(MPI_COMM_WORLD, &n);
    gethostname(hostname, 128);
    if (my_rank == 0) {
        /* master */
        printf("I am the master: %s\n", hostname);
    }
    else {
        /* worker */
        printf("I am a worker: %s (rank=\%d/%d)\n", hostname, my_rank, n-1);
    }
    MPI_Finalize();
    return 0;
}
```

[A. Snavely]→
Program Output

[negrut@euler04 CodeBits]$ mpiexec -np 8 ./a.out
I am a worker: euler04 (rank=1/7)
I am a worker: euler04 (rank=5/7)
I am a worker: euler04 (rank=6/7)
I am a worker: euler04 (rank=3/7)
I am a worker: euler04 (rank=4/7)
I am the master: euler04
I am a worker: euler04 (rank=2/7)
I am a worker: euler04 (rank=7/7)
[negrut@euler04 CodeBits]$
Why Care about MPI?

- Today, MPI is what enables supercomputers to run at PFlops rates
  - Some of these supercomputers might use GPU acceleration though

- Examples of architectures relying on MPI for HPC:
  - IBM Blue Gene L/P/Q (Argonne National Lab – “Mira”)
  - Cray supercomputers (Oakridge National Lab – “Titan”, also uses K20X GPUs)

- MPI has FORTRAN, C, and C++ bindings – widely used in Scientific Computing
MPI is a Standard

- MPI is an API for parallel programming on distributed memory systems. Specifies a set of operations, but says nothing about the implementation
  - MPI is a standard

- Popular because it many vendors support (implemented) it, therefore code that implements MPI-based parallelism is very portable

- One of the early common implementations: MPICH
  - The CH comes from Chameleon, the portability layer used in the original MPICH to provide portability to the existing message-passing systems
  - OpenMPI: a new kid on the block, joint effort of three or four groups (Los Alamos, Tennessee, Indiana University, Europe)
Where Can We Use Message Passing?

- Message passing can be used wherever it is possible for processes to exchange messages:
  - Distributed memory systems
  - Networks of Workstations
  - Even on shared memory systems
MPI vs. CUDA

- When would you use CPU/GPU computing and when would you use MPI-based parallel programming?
  - Use CPU/GPU
    - If your data fits the memory constraints associated with GPU computing
    - You have parallelism at a fine grain so that you the SIMD paradigm applies
    - Example:
      - Image processing
  - Use MPI-enabled parallel programming
    - If you have a very large problem, with a lot of data that needs to be spread out across several machines
    - Example:
      - Solving large heterogeneous multi-physics problems
- In large scale computing the future likely to belong to heterogeneous architecture
  - A collection of CPU cores that communicate through MPI, each or which farming out work to an accelerator (GPU)
MPI: A Second Example Application

- Example out of Pacheco’s book:
  - “Parallel Programming with MPI”
  - Good book, newer edition available

```c
/* greetings.c -- greetings program

* Send a message from all processes with rank != 0 to process 0.
  * Process 0 prints the messages received.

* Input: none.
* Output: contents of messages received by process 0.

* See Chapter 3, pp. 41 & ff in PPMPI.
*/
```
#include "mpi.h"
#include <stdio.h>
#include <string.h>

int main(int argc, char* argv[]) {
    int my_rank; /* rank of process */
    int p; /* number of processes */
    int source; /* rank of sender */
    int dest; /* rank of receiver */
    int tag = 0; /* tag for messages */
    char message[100]; /* storage for message */
    MPI_Status status; /* return status for receive */

    MPI_Init(&argc, &argv); // Start up MPI
    MPI_Comm_rank(MPI_COMM_WORLD, &my_rank); // Find out process rank
    MPI_Comm_size(MPI_COMM_WORLD, &p); // Find out number of processes

    if (my_rank != 0) {
        /* Create message */
        sprintf(message, "Greetings from process %d!", my_rank);
        dest = 0;
        /* Use strlen+1 so that '\0' gets transmitted */
        MPI_Send(message, strlen(message)+1, MPI_CHAR, dest, tag, MPI_COMM_WORLD);
    } else { /* my_rank == 0 */
        for (source = 1; source < p; source++) {
            MPI_Recv(message, 100, MPI_CHAR, source, tag, MPI_COMM_WORLD, &status);
            printf("%s\n", message);
        }
    }

    MPI_Finalize(); // Shut down MPI
    return 0;
} /* main */
Program Output

[negrut@euler CodeBits]$ mpiexec -np 8 ./greetingsMPI.exe
Greetings from process 1!
Greetings from process 2!
Greetings from process 3!
Greetings from process 4!
Greetings from process 5!
Greetings from process 6!
Greetings from process 7!
[negrut@euler CodeBits]$

MPI, a Third Example: Approximating $\pi$

\[
\int_0^1 \frac{4}{1 + x^2} = 4 \cdot \tan^{-1}(1) = \pi
\]

Numerical Integration: Midpoint rule

\[
\int_0^1 \frac{4}{1 + x^2} \approx \sum_{i=1}^{n} \frac{1}{n} f\left((i - 0.5) \cdot h\right)
\]
MPI, a Third Example: Approximating $\pi$

- Use 4 MPI processes (rank 0 through 3)
- In the picture, $n=13$
- Sub-intervals are assigned to ranks in a round-robin manner
  - Rank 0: 1,5,9,13
  - Rank 1: 2,6,10
  - Rank 2: 3,7,11
  - Rank 3: 4,8,12
- Each rank computes the area in its associated sub-intervals
- **MPIReduce** is used to sum the areas computed by each rank yielding final approximation to $\pi$
// MPI_PI.cpp : Defines the entry point for the console application.
//
#include "mpi.h"
#include <math.h>
#include <iostream>

using namespace std;

int main(int argc, char *argv[]) {
  int n, rank, size, i;
  double PI25DT = 3.141592653589793238462643;
  double mypi, pi, h, sum, x;
  char processor_name[MPI_MAX_PROCESSOR_NAME];
  int namelen;

  MPI_Init(&argc,&argv);
  MPI_Comm_size(MPI_COMM_WORLD,&size);
  MPI_Comm_rank(MPI_COMM_WORLD,&rank);
  MPI_Get_processor_name(processor_name, &namelen);

  cout << "Hello from process " << rank << " of " << size << " on " << processor_name << endl;
}
if (rank == 0) {
    //cout << "Enter the number of intervals: (0 quits) ";
    //cin >> n;
    if (argc<2 || argc>2)
        n=0;
    else
        n=atoi(argv[1]);
}

MPI_Bcast(&n, 1, MPI_INT, 0, MPI_COMM_WORLD);
if (n>0) {
    h = 1.0 / (double) n;
    sum = 0.0;
    for (i = rank + 1; i <= n; i += size) {
        x = h * ((double)i - 0.5);
        sum += (4.0 / (1.0 + x*x));
    }
    mypi = h * sum;

    MPI_Reduce(&mypi, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
    if (rank == 0)
        cout << "pi is approximately " << pi << " , Error is " << fabs(pi - PI25DT) << endl;
}

MPI_Finalize();
return 0;
Broadcast
[MPI function used in Example]

- A one-to-many communication.
Collective Communications

- Collective communication routines are higher level routines
- Several processes are involved at a time
- May allow **optimized internal** implementations, e.g., tree based algorithms
  - Require $O(\log(N))$ time as opposed to $O(N)$ for naïve implementation
Reduction Operations

[MPI function used in Example]

- Combine data from several processes to produce a single result
Barriers

- Used implicitly or explicitly to synchronize processes
MPI, Practicalities
MPI on Euler

[Selecting MPI Distribution]

- What’s available: OpenMPI, MVAPICH, MVAPICH2
- OpenMPI is default on Euler
  - This is the only one we’ll support in ME759

- To load OpenMPI environment variables:
  - (This should have been done automatically)

$ module load mpi/gcc/openmpi
MPI on Euler: [Compiling MPI Code via Cmake]

# Minimum version of CMake required.
cmake_minimum_required(VERSION 2.8)

# Set the name of your project
project(ME964-mpi)

# Include macros from the SBEL utils library
Include(ParallelUtils.cmake)

# Example MPI program
enable_mpi_support()
add_executable(integrate_mpi integrate_mpi.cpp)
target_link_libraries(integrate_mpi ${MPI_CXX_LIBRARIES})

find_package("MPI" REQUIRED)
list(APPEND CMAKE_C_COMPILE_FLAGS ${MPI_C_COMPILE_FLAGS})
list(APPEND CMAKE_C_LINK_FLAGS ${MPI_C_LINK_FLAGS})
include_directories(${MPI_C_INCLUDE_PATH})
list(APPEND CMAKE_CXX_COMPILE_FLAGS ${MPI_CXX_COMPILE_FLAGS})
list(APPEND CMAKE_CXX_LINK_FLAGS ${MPI_CXX_LINK_FLAGS})
include_directories(${MPI_CXX_INCLUDE_PATH})

Without the template
Replaces include(SBELUtils.cmake) and enable_mpi_support() above
Most MPI distributions provide wrapper scripts named `mpicc` or `mpicxx`

- Adds in `–L`, `–l`, `–I`, etc. flags for MPI
- Passes any options to your native compiler (`gcc`)
- Very similar to what `nvcc` did for CUDA – it’s a compile driver…

```
$ mpicxx -o integrate_mpi integrate_mpi.cpp
```
Running MPI Code on Euler

\texttt{mpiexec [-np #] [-machinefile file] <program> [<args>]}  

- Number of processors. Optional if using a machinefile
- List of hostnames to use. Inside Torque, this file is at $PBS\_NODEFILE$
- Your program and its arguments

- The machinefile/nodefile is required for multi-node jobs with the version of OpenMPI on Euler
- \texttt{-np} will be set automatically from the machinefile; can select lower, but not higher
- See the \texttt{mpiexec} manpage for more options
Example

euler $ qsub -I -l nodes=8:ppn=4:amd,walltime=5:00
euler: waiting for job 15246.euler to start
euler: job 15246.euler ready

euler07 $ cd $PBS_O_WORKDIR
euler07 $ mpiexec -machinefile $PBS_NODEFILE ./integrate_mpi
32 32.121040666358297 in 0.998202s

euler07 $ mpiexec -np 16 -machinefile $PBS_NODEFILE ./integrate_mpi
16 32.121040666359455 in 1.524001s

euler07 $ mpiexec -np 8 -machinefile $PBS_NODEFILE ./integratempi
8 32.121040666359136 in 2.171963s

euler07 $ mpiexec -np 4 -machinefile $PBS_NODEFILE ./integrate_mpi
4 32.121040666360585 in 4.600204s

euler07 $ mpiexec -np 2 -machinefile $PBS_NODEFILE ./integrate_mpi
2 32.121040666366788 in 7.615060s

euler07 $ ./integrate_mpi
1 32.121040666353437 in 15.163330s
Why do I get a compilation error "catastrophic error: #error directive: SEEK_SET is #defined but must not be for the C++ binding of MPI" when I compile C++ application?

- Define the `MPICH_IGNORE_CXX_SEEK` macro at compilation stage to avoid this issue. For instance,
  
  ```
  $ mpicc -DMPICH_IGNORE_CXX_SEEK
  ```

Why?

- There are name-space clashes between `stdio.h` and the MPI C++ binding. MPI standard requires `SEEK_SET`, `SEEK_CUR`, and `SEEK_END` names in the MPI namespace, but `stdio.h` defines them to integer values. To avoid this conflict make sure your application includes the `mpi.h` header file before `stdio.h` or `iostream.h` or undefine `SEEK_SET`, `SEEK_CUR`, and `SEEK_END` names before including `mpi.h`. 
MPI Nuts and Bolts
Goals/Philosophy of MPI

- MPI’s prime goals
  - Provide a message-passing interface for parallel computing
  - Make source-code portability a reality
  - Provide a set of services (building blocks) that increase developer’s productivity

- The philosophy behind MPI:
  - Specify a standard and give vendors the freedom to go about its implementation
  - Standard should be hardware platform & OS agnostic – key for code portability
The Rank, as a Facilitator for Data and Work Distribution

- To communicate together MPI processes need identifiers: \( \text{rank} = \text{identifying number} \)

- Work distribution decisions are based on the \textit{rank}
  - Helps establish which process works on which data
  - Just like we had thread and block indices in CUDA

\[ \text{myrank} = 0 \] data
\[ \text{myrank} = 1 \] data
\[ \text{myrank} = 2 \] data
\[ \text{myrank} = (\text{size}-1) \] data

communication network

\begin{center}
\begin{tikzpicture}
  \node[fill, circle, draw] (0) at (0,0) {\text{myrank}=0 data} node[below] {program};
  \node[fill, circle, draw] (1) at (1,0) {\text{myrank}=1 data} node[below] {program};
  \node[fill, circle, draw] (2) at (2,0) {\text{myrank}=2 data} node[below] {program};
  \node[fill, circle, draw] (3) at (3,0) {\text{myrank}=(\text{size}-1) data} node[below] {program};
  \draw (0) -- (1) -- (2) -- (3);
\end{tikzpicture}
\end{center}
Message Passing

- Messages are packets of data moving between different processes
- Necessary information for the message passing system:
  - sending process + receiving process \{ i.e., the two “ranks” \}
  - source location + destination location
  - source data type + destination data type
  - source data size + destination buffer size

[Diagram showing communication network and data flow]
#include "mpi.h"
#include <stdio.h>
#include <string.h>

int main(int argc, char* argv[]) {
    int my_rank; /* rank of process */
    int p; /* number of processes */
    int source; /* rank of sender */
    int dest; /* rank of receiver */
    int tag = 0; /* tag for messages */
    char message[100]; /* storage for message */
    MPI_Status status; /* return status for receive */

    MPI_Init(&argc, &argv); // Start up MPI
    MPI_Comm_rank(MPI_COMM_WORLD, &my_rank); // Find out process rank
    MPI_Comm_size(MPI_COMM_WORLD, &p); // Find out number of processes

    if (my_rank != 0) {
        /* Create message */
        sprintf(message, "Greetings from process %d!", my_rank);
        dest = 0;
        /* Use strlen+1 so that \0 gets transmitted */
        MPI_Send(message, strlen(message)+1, MPI_CHAR, dest, tag, MPI_COMM_WORLD);
    }
    else { /* my_rank == 0 */
        for (source = 1; source < p; source++) {
            MPI_Recv(message, 100, MPI_CHAR, source, tag, MPI_COMM_WORLD, &status);
            printf("%s\n", message);
        }
    }

    MPI_Finalize(); // Shut down MPI
    return 0;
} /* main */
Program Output

[negrut@euler CodeBits]$ mpiexec -np 8 ./greetingsMPI.exe
Greetings from process 1!
Greetings from process 2!
Greetings from process 3!
Greetings from process 4!
Greetings from process 5!
Greetings from process 6!
Greetings from process 7!
[negrut@euler CodeBits]$
Communicator  MPI_COMM_WORLD

- All processes of an MPI program are members of the default communicator MPI_COMM_WORLD

- MPI_COMM_WORLD is a predefined handle in mpi.h

- Each process has its own rank in a given communicator:
  - starting with 0
  - ending with (size-1)

- You can define a new communicator in case you find it useful
  - Use MPI_Comm_create call. Example creates the communicator DANS_COMM_WORLD

```c
MPI_Comm_create(MPI_COMM_WORLD, new_group, &DANS_COMM_WORLD);
```
MPI_Comm_create

- **Synopsis**

```c
int MPI_Comm_create(MPI_Comm comm, MPI_Group group, MPI_Comm *newcomm);
```

- **Input Parameters**
  - `comm` - communicator (handle)
  - `group` - subset of the family of processes making up the `comm` (handle)

- **Output Parameter**
  - `comm_out` - new communicator (handle)
Point-to-Point Communication

- Simplest form of message passing
- One process sends a message to another process
  - MPI_Send
  - MPI_Recv
- Sends and receives can be
  - Blocking
  - Non-blocking
  - More on this shortly
Point-to-Point Communication

- Communication between two processes
- Source process sends message to destination process
- Communication takes place within a communicator, e.g., `DANS_COMM_WORLD`
- Processes are identified by their ranks in the communicator
The Data Type

- A message contains a number of elements of some particular data type

- MPI data types:
  - Basic data type
  - Derived data types – more on this later

- Data type handles are used to describe the type of the data moved around

Example: message with 5 integers

**MPI_Send & MPI_Recv: The Eager and Rendezvous Flavors**

- If you send small messages, the content of the buffer is sent to the receiving partner immediately
  - Operation happens in “eager mode”

- If you send a large amount of data, the sender function waits for the receiver to post a receive before sending the actual data of the message

- Why this eager-rendezvous dichotomy?
  - Because of the size of the data and the desire to have a safe implementation
  - If you send a small amount of data, the MPI implementation can buffer the content and actually carry out the transaction later on when the receiving process asks for data
    - Can’t play this trick if you attempt to move around a huge chunk of data though
NOTE: Each implementation of MPI has a default value (which might change at run time) beyond which a larger MPI_Send stops acting “eager”
- The MPI standard doesn’t provide specifics
- You don’t know how large is too large…

Does it matter if it’s Eager or Rendezvous?
- In fact it does, sometimes the code can hang – example to come

Remark: In the message-passing paradigm for parallel programming you’ll always have to deal with the fact that the data that you send needs to “live” somewhere during the send-receive transaction
Moving away from the Eager vs. Rendezvous modes → they only concern the MPI_Send and MPI_Recv pair

Messages can be sent with other vehicles than plain vanilla MPI_Send

The class of send-receive operations can be classified based on whether they are blocking or non-blocking

- Blocking send: upon return from a send operation, you can modify the content of the buffer in which you stored data to be sent since a copy of the data has been sent

- Non-blocking: the send call returns immediately and there is no guarantee that the data has actually been transmitted upon return from send call
  - Take home message: before you modify the content of the buffer you better make sure (through a MPI status call) that the send actually completed
Example: Send & Receive

Non-blocking Alternative: MPI_Isend

- If non-blocking, the data “lives” in your buffer – that’s why it’s not safe to change it since you don’t know when transaction was closed
  - This typically realized through a MPI_Isend
    - “I” stands for “immediate”

- NOTE: there is another way for providing a buffer region but this alternative is blocking
  - Realized through MPI_Bsend
    - “B” stands for “buffered”
  - The problem here is that *you* need to provide this additional buffer that stages the transfer
    - Interesting question: how large should *that* staging buffer be?
  - Adding another twist to the story: if you keep posting non-blocking sends that are not matched by corresponding “MPI_Recv” operations, you are going to overflow this staging buffer
Example: Send & Receive Blocking Options (several of them)

- The plain vanilla MPI_Send & MPI_Recvieve pair is blocking
  - It’s safe to modify the data buffer upon return

- The problem with plain vanilla:
  - 1: when sending large messages, there is no overlap of compute & data movement
    - This is what we strived for when using “streams” in CUDA
  - 2: if not done properly, the processes executing the MPI code can hang

- There are several other flavors of send/receive operations, to be discussed later, that can help with concerns 1 and 2 above
The Mechanics of P2P Communication: Sending a Message

```c
int MPI_Send(void *buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm)
```

- **buf** is the starting point of the message with **count** elements, each described with **datatype**

- **dest** is the rank of the destination process within the communicator **comm**

- **tag** is an additional nonnegative integer piggyback information, additionally transferred with the message
  - The **tag** can be used to distinguish between different messages
  - Rarely used
The Mechanics of P2P Communication: Receiving a Message

```c
int MPI_Recv(void *buf, int count, MPI_Datatype datatype, int source, int tag,
             MPI_Comm comm, MPI_Status *status)
```

- **buf/count/datatype** describe the receive buffer
- Receiving the message sent by process with rank `source` in `comm`
- Only messages with matching `tag` are received
- Envelope information is returned in the `MPI_Status` object `status`
MPI_Recv:
The Need for an MPI_Status Argument

- The MPI_Status object returned by the call settles a series of questions:
  - The receive call does not specify the size of an incoming message, but only an upper bound.
  - If multiple requests are completed by a single MPI function, a distinct error code may need to be returned for each request.
  - The source or tag of a received message may not be known if wildcard values were used in a receive operation.
The Mechanics of P2P Communication: Wildcarding

- Receiver can wildcard
  - To receive from any source – source = MPI_ANY_SOURCE
  - To receive from any tag – tag = MPI_ANY_TAG
  - Actual source and tag returned in receiver's status argument
The Mechanics of P2P Communication: Communication Envelope

- Envelope information is returned from MPI_RECV in status.
  
  status.MPI_SOURCE
  status.MPI_TAG
  count via MPI_Get_count()

```c
int MPI_Get_count(MPI_Status *status, MPI_Datatype datatype, int *count);
```
For a communication to succeed:

- Sender must specify a valid destination rank
- Receiver must specify a valid source rank
- The communicator must be the same
- Tags must match
- Message data types must match
- Receiver’s buffer must be large enough
Blocking Type: Communication Modes

- Send communication modes:
  - Synchronous send \(\rightarrow\) MPI_SSEND
  - Buffered [asynchronous] send \(\rightarrow\) MPI_BSEND
  - Standard send \(\rightarrow\) MPI_SEND
  - Ready send \(\rightarrow\) MPI_RSEND

- Receiving all modes \(\rightarrow\) MPI_RECV

</table>
1) Synchronous Sending in MPI
2) Buffered Sending in MPI

- **Synchronous with MPI_Ssend**
  - In synchronous mode, a send will not complete until a matching receive is posted.
  - The sender has to wait for a receive to be posted
  - No buffering of data
  - Used for ensuring the code is healthy and doesn’t rely on buffering

- **Buffered with MPI_Bsend**
  - Send completes once message has been buffered internally by MPI
  - Buffering incurs an extra memory copy
  - Does not require a matching receive to be posted
  - May cause buffer overflow if many bsends and no matching receives have been posted yet
3) Standard Sending in MPI
4) Ready Sending in MPI

- **Standard with MPI_Send**
  - Up to the MPI implementation to decide whether to do rendezvous or eager, for performance reasons
    - **NOTE:** If it does rendezvous, in fact the behavior is that of MPI_SSend
  - Very commonly used

- **Ready with MPI_Rsend**
  - Will work correctly *only* if the matching receive has been posted
  - Can be used to avoid handshake overhead when program is known to meet this condition
  - Rarely used, can cause major problems
Most Important Issue: Deadlocking

- Deadlock situations: appear when due to a certain sequence of commands the execution hangs

```
... Process 0
MPI_Ssend()
MPI_Recv()
...
...
MPI_Buffer_attach()
MPI_Bsend()
MPI_Recv()
...
...
MPI_Buffer_attach()
MPI_Bsend()
MPI_Recv()
...
...

No Deadlock
```

```
... Process 1
MPI_Ssend()
MPI_Recv()
...
...
MPI_Buffer_attach()
MPI_Bsend()
MPI_Recv()
...
...
MPI_Buffer_attach()
MPI_Bsend()
MPI_Recv()
...
...

No Deadlock
```
Deadlocking, Another Example

- **MPI_Send** can respond in eager or rendezvous mode
- Example, on a certain machine running MPICH v1.2.1:

  ```
  Process 0
  ...
  MPI_Send()
  MPI_Recv()
  ...

  No Deadlock
  Data size > 127999 bytes
  Data size < 128000 bytes
  Deadlock

  Process 1
  ...
  MPI_Send()
  MPI_Recv()
  ...
  ```
Avoiding Deadlocking

- Easy way to eliminate deadlock is to pair `MPI_Ssend` and `MPI_Recv` operations the right way:
  
  ```
  ... MPI_Ssend() MPI_Recv() ...
  ...
  ```

- Conclusion: understand how the implementation works and what its pitfalls/limitations are
Example

- Always succeeds, even if no buffering is done

```c
if(rank==0)
{
    MPI_Send(...);
    MPI_Recv(...);
}
else if(rank==1)
{
    MPI_Recv(...);
    MPI_Send(...);
}
```
Example

- Will always deadlock, no matter the buffering mode

```c
if(rank==0)
{
    MPI_Recv(...);
    MPI_Send(...);
}
else if(rank==1)
{
    MPI_Recv(...);
    MPI_Send(...);
}
```
Example

- Only succeeds if message is at least one of the transactions is small enough and an “eager” mode is triggered

```c
if(rank==0)
{
    MPI_Send(...);
    MPI_Recv(...);
}
else if(rank==1)
{
    MPI_Send(...);
    MPI_Recv(...);
}
```
Concluding Remarks, Blocking Options

- Standard send (MPI_SEND)
  - minimal transfer time
  - may block due to synchronous mode
  - → risks with synchronous send

- Synchronous send (MPI_SSEND)
  - risk of deadlock
  - risk of serialization
  - risk of waiting → idle time
  - high latency / best bandwidth

- Buffered send (MPI_BSEND)
  - low latency / bad bandwidth

- Ready send (MPI_RSEND)
  - use never, except you have a 200% guarantee that Recv is already called in the current version and all future versions of your code
Technicalities, Loose Ends: More on the Buffered Send

- Relies on the existence of a buffer, which is set up through a call:
  ```c
  int MPI_Buffer_attach(void* buffer, int size);
  ```

- A bsend is a **local** operation. It does not depend on the occurrence of a matching receive in order to complete.

- If a bsend operation is started and no matching receive is posted, the outgoing message is buffered to allow the send call to complete.

- Return from an **MPI_Bsend** does not guarantee the message was sent.

- Message may remain in the buffer until a matching receive is posted.
Technicalities, Loose Ends: More on the Buffered Send [Cntd.]

- Make sure you have enough buffer space available. An error occurs if the message must be buffered and there is not enough buffer space.

- The amount of buffer space needed to be safe depends on the expected peak of pending messages. The sum of the sizes of all of the pending messages at that point plus (MPI_BSEND_OVERHEAD*number_of_messages) should be sufficient.

- **MPI_Bsend** lowers bandwidth since it requires an extra memory-to-memory copy of the outgoing data.

- The **MPI_Buffer_attach** subroutine provides MPI a buffer in the user's memory. This buffer is used only by messages sent in buffered mode, and only one buffer is attached to a process at any time.
Technicalities, Loose Ends: Message Order Preservation

- Rule for messages on the same connection; i.e., same communicator, source, and destination rank:
  - Messages do not overtake each other
  - True even for non-synchronous sends

- If both receives match both messages, then the order is preserved
Read This for Assignment 11

- Write a program according to the time-line diagram:
  - process 0 sends a message to process 1 (ping)
  - after receiving this message, process 1 sends a message back to process 0 (pong)

- Repeat this ping-pong with a loop of length 50

- Add timing calls before and after the loop

- For timing purposes, you might want to use
  ```
  double MPI_Wtime();
  ```

- `MPI_Wtime` returns a wall-clock time in seconds

- At process 0, print out the transfer time in seconds
  - Might want to use a log scale
More on Timing
[Useful, for Assignment 11]

```c
int main()
{
    double starttime, endtime;
    starttime = MPI_Wtime();
    .... stuff to be timed ... 
    endtime = MPI_Wtime();
    printf("That took %f seconds\n", endtime - starttime);
    return 0;
}
```

- Resolution is typically 1E-3 seconds
- Time of different processes might actually be synchronized, controlled by the variable `MPI_WTIME_IS_GLOBAL`
More on Timing
[Useful, for Assignment 11; Cntd.]

- Latency = transfer time for zero length messages
- Bandwidth = message size (in bytes) / transfer time

- Message transfer time and bandwidth change based on the nature of the MPI send operation
  - Standard send (MPI_Send)
  - Synchronous send (MPI_Ssend)
  - Buffered send (MPI_Bsend)
  - Etc.
Non-Blocking Communication
Non-Blocking Communications: Motivation

- Overlap communication with execution (just like w/ CUDA):
  - Initiate non-blocking communication
    - Returns Immediately
    - Routine name starting with MPI_I...
  - Do some work
    - “latency hiding”
  - Wait for non-blocking communication to complete
Non-blocking Send/Receive

• Syntax

```c
int MPI_Isend(void *buf, int count, MPI_Datatype datatype, int dest, int tag,
               MPI_Comm comm, MPI_Request *request);
```

- buf - [in] initial address of send buffer (choice)
- count - [in] number of elements in send buffer (integer)
- datatype - [in] datatype of each send buffer element (handle)
- dest - [in] rank of destination (integer)
- tag - [in] message tag (integer)
- comm - [in] communicator (handle)
- request - [out] communication request (handle)

```c
int MPI_Irecv(void *buf, int count, MPI_Datatype datatype, int source, int tag,
               MPI_Comm comm, MPI_Request *request);
```
The Screenplay: Non-Blocking P2P Communication

- Non-blocking send
  - MPI_Isend(...) doing some other work
  - MPI_Wait(...) = waiting until operation locally completed

- Non-blocking receive
  - MPI_Irecv(...) doing some other work
  - MPI_Wait(...) = waiting until operation locally completed

// = waiting until operation locally completed
Non-Blocking Send/Receive

Some Tools of the Trade

- Call returns immediately. Therefore, user must worry whether …
  - Data to be sent is out of the send buffer before trampling on the buffer
  - Data to be received has finished arriving before using the content of the buffer

- Tools that come in handy:
  - For sends and receives in flight
    - `MPI_Wait` – blocking - you go synchronous
    - `MPI_Test` – non-blocking - returns quickly with status information

- Check for existence of data to receive
  - Blocking: `MPI_Probe`
  - Non-blocking: `MPI_Iprobe`
Waiting for isend/ireceive to Complete

- Waiting on a single send
  ```c
  int MPI_Wait(MPI_Request *request, MPI_Status *status);
  ```

- Waiting on multiple sends (get status of all)
  - Till all complete, as a barrier
    ```c
    int MPI_Waitall(int count, MPI_Request *requests, MPI_Status *statuses);
    ```
  - Till at least one completes
    ```c
    int MPI_Waitany(int count, MPI_Request *requests, int *index, MPI_Status *status);
    ```
  - Helps manage progressive completions
    ```c
    int MPI_Waitsome(int incount, MPI_Request *requests, int *outcount,
                     int *indices, MPI_Status *statuses);
    ```
**MPI_Test...**

- Flag true means completed

```c
int MPI_Test(MPI_Request *request, int *flag, MPI_Status *status);
```

```c
int MPI_Testall(int count, MPI_Request *requests, int *flag, MPI_Status *statuses);
```

```c
int MPI_Testany(int count, MPI_Request *requests, int *index, int *flag, MPI_Status *status);
```

- Like a non blocking MPI_Waitsome

```c
int MPI_Testsome(int incount, MPI_Request *requests, int *outcount, int *indices, MPI_Status *statuses);
```
The Need for MPI_Probe and MPI_Iprobe

- The **MPI_PROBE** and **MPI_IPROBE** operations allow incoming messages to be checked for, without actually receiving them.

- The user can then decide how to receive them, based on the information returned by the probe (basically, the information returned by status).

- In particular, the user may allocate memory for the receive buffer, according to the length of the probed message.
Probes yield incoming size

- Blocking Probe, wait till match
  ```c
  int MPI_Probe(int source, int tag, MPI_Comm comm, MPI_Status *status);
  ```

- Non Blocking Probe, flag true if ready
  ```c
  int MPI_Iprobe(int source, int tag, MPI_Comm comm, int *flag, MPI_Status *status);
  ```
Two types of communication:

- Blocking:
  - Safe to change content of buffer holding on to data in the MPI send call
- Non-blocking:
  - Be careful with the data in the buffer, since you might step on/use it too soon

MPI provides four modes for these two types
- standard, synchronous, buffered, ready
Collective Actions
Collective Actions

- MPI actions involving a group of processes
- Must be called by all processes in a communicator
- All collective actions are blocking

Types of Collective Actions (three of them):
- Global Synchronization (barrier synchronization)
- Global Communication (broadcast, scatter, gather, etc.)
- Global Operations (sum, global maximum, etc.)
Barrier Synchronization

- Syntax:

```c
int MPI_Barrier(MPI_Comm comm);
```

- **MPI_Barrier** not needed that often:
  - All synchronization is done automatically by the data communication
    - A process cannot continue before it has the data that it needs
  - If used for debugging
    - Remember to remove for production release
Communication Action: Broadcast

- Function prototype:

```c
int MPI_Bcast( void *buf, int count, MPI_Datatype datatype, int root, MPI_Comm comm);
```

- rank of the sending process (i.e., root process)
- must be given identically by all processes
MPI_Bcast

$A_0$ : any chunk of contiguous data described with MPI_Datatype and count
MPI_Bcast

```c
int MPI_Bcast (void *buffer, int count, MPI_Datatype type, int root, MPI_Comm comm);
```

- **INOUT**: `buffer` (starting address, as usual)
- **IN**: `count` (number of entries in buffer)
- **IN**: `type` (can be user-defined)
- **IN**: `root` (rank of broadcast root)
- **IN**: `com` (communicator)

- Broadcasts message from `root` to all processes (including `root`)
- `com` and `root` must be identical on all processes
- On return, contents of `buffer` is copied to all processes in `com`
Example: MPI_Bcast

- Read a parameter file on a single processor and send data to all processes

```c
#include "mpi.h"
#include <assert.h>
#include <stdlib.h>

int main(int argc, char **argv){
    int myRank, nprocs;
    float data = -1.0;
    FILE *file;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myRank);

    if( myRank==0 ) {
        char input[100];
        file = fopen("data1.txt", "r");
        assert (file != NULL);
        fscanf(file, "%s\n", input);
        data = atof(input);
    }
    printf("data before: %f\n", data);
    MPI_Bcast(&data, 1, MPI_FLOAT, 0, MPI_COMM_WORLD);
    printf("data after: %f\n", data);

    MPI_Finalize();
}
```
Example: MPI_Bcast

[Output]

[negrut@euler CodeBits]$ qsub -l nodes=8:ppn=4,walltime=5:00
qsub: waiting for job 16114.euler to start
qsub: job 16114.euler ready

E
MPI_Gather

- Processes:
  - $A_0$
  - $A_1$
  - $A_2$
  - $A_3$
  - $A_4$
  - $A_5$

- Data:
  - $A_0$
  - $A_1$
  - $A_2$
  - $A_3$
  - $A_4$
  - $A_5$

- Data (buffer):
  - $A_0$
  - $A_1$
  - $A_2$
  - $A_3$
  - $A_4$
  - $A_5$
MPI_Gather

```c
int MPI_Gather (void *sendbuf, int sendcount, MPI_Datatype sendtype, 
                void *recvbuf, int recvcount, MPI_Datatype recvtype, int root, MPI_Comm comm);
```

- **IN** `sendbuf` (starting address of send buffer)
- **IN** `sendcount` (number of elements in send buffer)
- **IN** `sendtype` (type)
- **OUT** `recvbuf` (address of receive buffer)
- **IN** `recvcount` (n-elements **for any single receive**)
- **IN** `recvtype` (data type of recv buffer elements)
- **IN** `root` (rank of receiving process)
- **IN** `comm` (communicator)
**MPI_Gather**

- Each process sends content of send buffer to the root process
- Root receives and stores in rank order
- Remarks:
  - Receive buffer argument ignored for all non-root processes (also recvtype, etc.)
  - `recvcount` on root indicates number of items received from each process, not total. This is a very common error
- Exercise: Sketch an implementation of **MPI_Gather** using only send and receive operations.
#include "mpi.h"
#include <stdlib.h>

int main(int argc, char **argv){
    int myRank, nprocs, nlcl=2, n, i;
    float *data, *data_loc;

    MPI_Init(&argc, &argv);

Communication Action: Scatter

- Function prototype

```c
int MPI_Scatter (void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf,
                 int recvcount, MPI_Datatype recvtype, int root, MPI_Comm comm);
```

![Diagram showing before and after scatter]

- e.g., root=1

  *before scatter*

  ![Before scatter diagram]

  *after scatter*

  ![After scatter diagram]
MPI_Scatter

![Diagram of MPI_Scatter process and data distribution](image)
MPI_Scatter

int MPI_Scatter (void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf, int recvcount, MPI_Datatype recvtype, int root, MPI_Comm comm);

- **IN** sendbuf (starting address of send buffer)
- **IN** sendcount (number of elements sent to each process)
- **IN** sendtype (type)
- **OUT** recvbuf (address of receive buffer)
- **IN** recvcount (n-elements in receive buffer)
- **IN** recvtype (data type of receive elements)
- **IN** root (rank of sending process)
- **IN** comm (communicator)
MPI_Scatter

- Inverse of MPI_Gather

- Data elements on root listed in rank order – each processor gets corresponding data chunk after call to scatter

- Remarks:
  - All arguments are significant on root, while on other processes only recvbuf, recvcount, recvtype, root, and comm are significant
```c
#include "mpi.h"
#include <stdlib.h>

int main(int argc, char **argv){
    int myRank, nprocs, n_lcl=2;
    float *data, *data_l;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myRank);

    /* local array size on each proc = n_lcl */
data_l = (float *) malloc(n_lcl*sizeof(float));

    if( myRank==0 ) {
        data = (float *) malloc(nprocs*sizeof(float)*n_lcl);
        for( int i = 0; i < nprocs*n_lcl; ++i) data[i] = i;
    }

    MPI_Scatter(data, n_lcl, MPI_FLOAT, data_l, n_lcl, MPI_FLOAT, 0, MPI_COMM_WORLD);

    for( int n=0; n < nprocs; ++n ){
        if( myRank==n ){
            for (int j = 0; j < n_lcl; ++j) printf("%f\n", data_l[j]);
        }
        MPI_Barrier(MPI_COMM_WORLD);
    }

    MPI_Finalize();
    return 0;
}
```

This is interesting. Think what's happening here...

Putting Things in Perspective...

- **Gather**: you automatically create a serial array from a distributed one

- **Scatter**: you automatically create a distributed array from a serial one
Global Reduction Operations

- To perform a global reduce operation across all members of a group.
- \(d_0 \circ d_1 \circ d_2 \circ d_3 \circ \ldots \circ d_{s-2} \circ d_{s-1}\)
  - \(d_i = \) data in process rank \(i\)
    - single variable, or
    - vector
  - \(\circ =\) associative operation
  - Example:
    - global sum or product
    - global maximum or minimum
    - global user-defined operation

- Floating point rounding may depend on usage of associative law:
  - \([(d_0 \circ d_1) \circ (d_2 \circ d_3)] \circ […] \circ (d_{s-2} \circ d_{s-1})]\)
  - \((((((d_0 \circ d_1) \circ d_2) \circ d_3) \circ […] \circ d_{s-2}) \circ d_{s-1})\)
Example of Global Reduction

- Global integer sum
- Sum of all inbuf values should be returned in resultbuf.
- Assume root=0;

MPI_Reduce(&inbuf, &resultbuf, 1, MPI_INT, MPI_SUM, root, MPI_COMM_WORLD);

- The result is only placed in resultbuf at the root process.

Reduce Operation

Assumption: Rank 0 is the root
MPI_Reduce

```c
int MPI_Reduce (void *sendbuf, void *recvbuf, int count,
                MPI_Datatype datatype, MPI_Op op, int root, MPI_Comm comm);
```

- **IN** `sendbuf` (address of send buffer)
- **OUT** `recvbuf` (address of receive buffer)
- **IN** `count` (number of elements in send buffer)
- **IN** `datatype` (data type of elements in send buffer)
- **IN** `op` (reduce operation)
- **IN** `root` (rank of root process)
- **IN** `comm` (communicator)
MPI_Reduce example

**MPI_Reduce** (sbuf, rbuf, 6, MPI_INT, MPI_SUM, 0, MPI_COMM_WORLD)

\[
\begin{align*}
\text{sbuf} & : P0 \quad 3 \quad 4 \quad 2 \quad 8 \quad 12 \quad 1 \\
& \quad P1 \quad 5 \quad 2 \quad 5 \quad 1 \quad 7 \quad 11 \\
& \quad P2 \quad 2 \quad 4 \quad 4 \quad 10 \quad 4 \quad 5 \\
& \quad P3 \quad 1 \quad 6 \quad 9 \quad 3 \quad 1 \quad 1 \\
\end{align*}
\]

\[
\begin{align*}
\text{rbuf} & : P0 \quad 11 \quad 16 \quad 20 \quad 22 \quad 24 \quad 18 \\
\end{align*}
\]
**MPI_Reduce, MPI_Allreduce**

- **MPI_Reduce**: result is collected by the root only
  - The operation is applied element-wise for each element of the input arrays on each processor

- **MPI_Allreduce**: result is sent out to everyone

```c
MPI_Reduce(x, r, 10, MPI_INT, MPI_MAX, 0, MPI_COMM_WORLD)
```

```c
MPI_Allreduce(x, r, 10, MPI_INT, MPI_MAX, MPI_COMM_WORLD)
```

MPI_SCAN

- Performs a prefix reduction on data distributed across a communicator.

- The operation returns, in the receive buffer of the process with rank \( i \), the reduction of the values in the send buffers of processes with ranks \( 0, \ldots, i \) (inclusive).

- The type of operations supported, their semantics, and the constraints on send and receive buffers are as for `MPI_REDUCE`.

MPI_Scan: Prefix reduction

- Process i receives data reduced on process 0 through i

\[ \text{MPI}_\text{Scan}(\text{sbuf}, \text{rbuf}, 6, \text{MPI}_\text{INT}, \text{MPI}_\text{SUM}, \text{MPI}_\text{COMM}_\text{WORLD}) \]
MPI_Scan

```
int MPI_Scan (void *sendbuf, void *recvbuf, int count,
             MPI_Datatype datatype, MPI_Op op, MPI_Comm comm);
```

- **IN** `sendbuf` (address of send buffer)
- **OUT** `recvbuf` (address of receive buffer)
- **IN** `count` (number of elements in send buffer)
- **IN** `datatype` (data type of elements in send buffer)
- **IN** `op` (reduce operation)
- **IN** `comm` (communicator)

*Note: `count` refers to total number of elements that will be received into receive buffer after operation is complete*
```c
#include "mpi.h"
#include <stdio.h>
#include <stdlib.h>

int main(int argc, char **argv){
    int myRank, nprocs, i, n;
    int *result, *data_l;
    const int dimArray = 2;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myRank);

    data_l = (int *) malloc(dimArray*sizeof(int));
    for (i = 0; i < dimArray; ++i) data_l[i] = (i+1)*myRank;
    for (n = 0; n < nprocs; ++n) {
        if( myRank == n ) {
            for(i=0; i<dimArray; ++i) printf("Process %d. Entry: %d.  Value: %d\n", myRank, i, data_l[i]);
            printf("\n");
        }
        MPI_Barrier(MPI_COMM_WORLD);
    }

    result = (int *) malloc(dimArray*sizeof(int));
    MPI_Scan(data_l, result, dimArray, MPI_INT, MPI_SUM, MPI_COMM_WORLD);
    for (n = 0; n < nprocs; ++n){
        if (myRank == n) {
            printf("\n Post Scan - Content on Process: %d\n", myRank);
            for (i = 0; i < dimArray; ++i) printf("Entry: %d. Scan Val: %d\n", i, result[i]);
        }
        MPI_Barrier(MPI_COMM_WORLD);
    }
    MPI_Finalize();
    free(result); free(data_l);
    return 0;
}
```
Example: MPI_Scan

[Output]

```bash

**MPI_Exscan**

- **MPI_Exscan** is like **MPI_Scan**, except that the contribution from the calling process is not included in the result at the calling process (it is contributed to the subsequent processes).
- The value in `recvbuf` on the process with rank 0 is undefined, and `recvbuf` is not significant on process 0.
- The value in `recvbuf` on the process with rank 1 is defined as the value in `sendbuf` on the process with rank 0.
- For processes with rank `i > 1`, the operation returns, in the receive buffer of the process with rank `i`, the reduction of the values in the send buffers of processes with ranks 0,...,i-1 (inclusive).
- The type of operations supported, their semantics, and the constraints on send and receive buffers, are as for **MPI_REDUCE**.
MPI_Exscan

```c
int MPI_Exscan (void *sendbuf, void *recvbuf, int count,
                MPI_Datatype datatype, MPI_Op op, MPI_Comm comm);
```

- **IN** `sendbuf`  (address of send buffer)
- **OUT** `recvbuf`  (address of receive buffer)
- **IN** `count`    (number of elements in send buffer)
- **IN** `datatype` (data type of elements in send buffer)
- **IN** `op`       (reduce operation)
- **IN** `comm`     (communicator)
#include "mpi.h"
#include <stdio.h>
#include <stdlib.h>

int main(int argc, char **argv){
    int myRank, nprocs,i, n;
    int *result, *data_l;
    const int dimArray = 2;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myRank);

    data_l = (int *) malloc(dimArray*sizeof(int));

[negrut@euler26 CodeBits]$
User-Defined Reduction Operations

- Operator handles
  - Predefined – see table of last lecture: MPI_SUM, MPI_MAX, etc.
  - User-defined

- User-defined operation:
  - Should be associative
  - User-defined function must perform the operation “vector_A \oplus vector_B”

- Registering a user-defined reduction function:

    MPI_Op_create( MPI_User_function *func, int commute, MPI_Op *op);

- `commute` tells the MPI library whether `func` is commutative or not
Example:
Norm 1 of a Vector

```c
#include <mpi.h>
#include <stdio>
#include <math.h>

void oneNorm(float *in, float *inout, int *len,
             MPI_Datatype *type)
{
    int i;
    for (i=0; i<*len; i++) {
        *inout = fabs(*in) + fabs(*inout);    /* one-norm */
        in++; inout++;
    }
}
```

```c
int main(int argc, char* argv[]) { int root=0, p, myid; float sendbuf, recvbuf; MPI_Op myop;

    int commutes=1;
    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &p);
    MPI_Comm_rank(MPI_COMM_WORLD, &myid);

    //create the operator...
    MPI_Op_create(onenorm, commune, &myop);

    //get some fake data used to make the point...
    sendbuf = myid*(-1)^myid;
    MPI_Barrier(MPI_COMM_WORLD);

    MPI_Reduce (&sendbuf, &recvbuf, 1, MPI_FLOAT, myop, root,
                MPI_COMM_WORLD);
    if( myid == root )
        printf("The operation yields %f\n", recvbuf);
    MPI_Finalize();
    return 0;
}
```
#include <thrust/transform_reduce.h>
#include <thrust/device_vector.h>
#include <thrust/host_vector.h>
#include <cmath>

template <typename T>
struct absval {
    __host__ __device__
    T operator()(const T& x) const {
        return fabs(x);
    }
};

int main(void) {
    // initialize host array
    float x[4] = {1.0, -2.0, 3.0, -4.0};

    // transfer to device
    thrust::device_vector<float> d_x(x, x + 4);

    absval<float> unary_op;
    float res = thrust::transform_reduce(d_x.begin(), d_x.end(), unary_op, 0.f, thrust::plus<float>());

    std::cout << res << std::endl;
    return 0;
}
MPI Derived Types
[Describing Non-contiguous and Heterogeneous Data]
The Relevant Question

- The relevant question that we want to be able to answer?
  - “What’s in your buffer?”

- Communication mechanisms discussed so far allow send/recv of a contiguous buffer of identical elements of predefined data types

- Often want to send non-homogenous elements (structure) or chunks that are not contiguous in memory

- MPI enables you to define derived data types to answer the question “What’s in your buffer?”
MPI Datatypes

- MPI Primitive Datatypes
  - `MPI_Int`, `MPI_Float`, `MPI_INTEGER`, etc.

- Derived Data types - can be constructed by four methods:
  - contiguous
  - vector
  - indexed
  - struct
  - Can be subsequently used in all point-to-point and collective communication

- The motivation: create your own types to suit your needs
  - More convenient
  - More efficient
Type Maps

A derived data type specifies two things:
- A sequence of primitive data types
- A sequence of integers that represent the byte displacements, measured from the beginning of the buffer

Displacements are not required to be positive, distinct, or in increasing order (however, negative displacements will precede the buffer)

Order of items need not coincide with their order in memory, and an item may appear more than once
# Type Map

<table>
<thead>
<tr>
<th>Primitive datatype 0</th>
<th>Displacement of 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primitive datatype 1</td>
<td>Displacement of 1</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Primitive datatype n-1</td>
<td>Displacement of n-1</td>
</tr>
</tbody>
</table>
**Extent**

[Jargon]

- Extent: distance, in bytes, from beginning to end of type

- More specifically, the *extent* of a data type is defined as:
  … the span from the first byte to the last byte occupied by entries in this data type *rounded up to satisfy alignment requirements*

- Example:
  - Type={**double**,0},**(char,8)** i.e. offsets of 0 and 8 respectively.
  - Now assume that doubles are aligned strictly at addresses that are multiples of 8
  - extent = 16 (9 rounds to next multiple of 8, which is where the next double would land)
Map Type, Examples

- What is extent of type {(char, 0), (double, 8)}?  
  Ans: 16

- Is this a valid type: {(double, 8), (char, 0)}?  
  Ans: yes, since order does not matter
Example

- What is Type Map of `MPI_INT`, `MPI_DOUBLE`, etc.?
  - `{(int,0)}`
  - `{(double, 0)}`
  - Etc.
Type Signature

[Jargon]

- The **sequence** of primitive data types (i.e. displacements ignored) is the **type signature** of the data type

- Example: a type map of
  
  \{(\text{double}, 0), (\text{int}, 8), (\text{char}, 12)\}

- ...has a type signature of
  
  \{\text{double, int, char}\}
Data Type Interrogators

```c
int MPI_Type_extent (MPI_Datatype datatype, MPI_Aint *extent);
```

- **datatype** - primitive or derived **datatype**
- **extent** - returns extent of **datatype** in bytes

```c
int MPI_Type_size (MPI_Datatype datatype, int *size);
```

- **datatype** - primitive or derived **datatype**
- **size** - returns size in bytes of the entries in the **type signature** of **datatype**
  - Gaps don’t contribute to size
  - This is the total size of the data in a message that would be created with this **datatype**
  - Entries that occur multiple times in the **datatype** are counted with their multiplicity

**MPI_Aint** - C type that holds any valid address
Committing Data Types

- Each derived data type constructor returns an *uncommited* data type. Think of commit process as a compilation of data type description into efficient internal form

```c
int MPI_Type_commit (MPI_Datatype *datatype);
```

- **Required** for any derived data type before it can be used in communication

- Subsequently can use in any function call where an `MPI_Datatype` is specified
MPI_Type_free

```c
int MPI_Type_free(MPI_Datatype *datatype);
```

- Call to `MPI_Type_free` sets the value of an MPI data type to `MPI_DATATYPE_NULL`
- Data types that were derived from the defined data type are unaffected.
MPI Type-Definition Functions

[“constructors”]

- **MPI_Type_Contiguous**: a replication of data type into contiguous locations
- **MPI_Type_vector**: replication of data type into locations that consist of equally spaced blocks
- **MPI_Type_create_hvector**: like vector, but successive blocks are not multiple of base type extent
- **MPI_Type_indexed**: non-contiguous data layout where displacements between successive blocks need not be equal
- **MPI_Type_create_struct**: most general – each block may consist of replications of different data types

The inconsistent naming convention is unfortunate but carries no deeper meaning. It is a compatibility issue between old and new version of MPI.
MPI_Type_contiguous

```c
int MPI_Type_contiguous(int count, MPI_Datatype oldtype, MPI_Datatype *newtype);
```

- **IN** count (replication count)
- **IN** oldtype (base data type)
- **OUT** newtype (handle to new data type)

- Creates a new type which is simply a replication of old type into contiguous locations
```c
#include <stdio.h>
#include <mpi.h>

/* !!! Should be run with at least four processes !!! */
int main(int argc, char *argv[]) {
    int rank;
    MPI_Status status;
    struct {
        int x;
        int y;
        int z;
    } point;
    MPI_Datatype ptype;

    MPI_Init(&argc,&argv);
    MPI_Comm_rank(MPI_COMM_WORLD,&rank);

    MPI_Type_contiguous(3,MPI_INT,&ptype);
    MPI_Type_commit(&ptype);
    if( rank==3 ){
        point.x=15; point.y=23; point.z=6;
        MPI_Send(&point,1,ptype,1,52,MPI_COMM_WORLD);
    } else if( rank==1 ) {
        MPI_Recv(&point,1,ptype,3,52,MPI_COMM_WORLD,&status);
        printf("P:%d received coords are (%d,%d,%d) \n",rank,point.x,point.y,point.z);
    }
    MPI_Type_free(&ptype);
    MPI_Finalize();
    return 0;
}
```
Example: MPI_Type_contiguous

[Output]

```
[negrut@euler24 CodeBits]$ mpiexec -np 10 me759.exe
P:1 received coords are (15,23,6)
[negrut@euler24 CodeBits]$
```
Motivation: MPI_Type_vector

- Assume you have a 2D array of integers, and want send the last column

```c
int x[4][8];
```

Content of `x`:

- There should be a way to say that I want to transfer integers, 4 of them, and they are stored in array `x` 8 integers apart (the stride)
MPI_Type_vector: Example

- oldtype
  - 5 element stride between blocks
- newtype
  - 3 elements per block
  - 2 blocks
- count = 2
- blocklength = 3
- stride = 5
**MPI_Type_vector**

- **MPI_Type_vector** is a constructor that allows replication of a data type into locations that consist of equally spaced blocks.

- Each block is obtained by concatenating the same number of copies of the old data type.

- Spacing between blocks is a multiple of the extent of the old data type.

- One way to look at it:
  - You want some entries but don’t care about other entries in an array.
  - There is a repeatability to this pattern of “wanted” and “not wanted” entries.
MPI_Type_vector

MPI_Type_vector (int count, int blocklength, int stride, MPI_Datatype oldtype, MPI_Datatype *newtype);

- IN count (number of blocks)
- IN blocklength (number of elements per block)
- IN stride (spacing between start of each block, measured as # elements)
- IN oldtype (base datatype)
- OUT newtype (handle to new type)

- Allows replication of old type into locations of equally spaced blocks. Each block consists of same number of copies of oldtype with a stride that is multiple of extent of old type
```c
#include <mpi.h>
#include <math.h>
#include <stdio.h>

int main(int argc, char *argv[]) {
    int rank,i,j;
    MPI_Status status;
    double x[4][8];
    MPI_Datatype coltype;

    MPI_Init(&argc, &argv);
    MPI_Comm_rank(MPI_COMM_WORLD,&rank);

    MPI_Type_vector(4,1,8,MPI_DOUBLE,&coltype);
    MPI_Type_commit(&coltype);

    if(rank==3){
        for(i=0;i<4;++i)
            for(j=0;j<8;++j) x[i][j]=pow(10.0,i+1)+j;
        MPI_Send(&x[0][7],1,coltype,1,52,MPI_COMM_WORLD);
    }
    else if(rank==1) {
        MPI_Recv(&x[0][2],1,coltype,3,52,MPI_COMM_WORLD,&status);
        for(i=0;i<4;++i)printf("P:%d my x[%d][2]=%1f\n",rank,i,x[i][2]);
    }
    MPI_Type_free(&coltype);
    MPI_Finalize();
    return 0;
}
```
Example: MPI_Type_vector

Output:

Content of x:

Example: MPI_Type_vector

- Given: Local 2D array of interior size $m \times n$ with $n_g$ ghostcells at each edge
- You wish to send the interior (non ghostcell) portion of the array
- How would you describe the data type to do this in a single MPI call?

```c
MPI_Type_vector(int count, int blocklength, int stride, MPI_Datatype oldtype, MPI_Datatype *newtype);
```

Ans:

```c
MPI_Type_vector(m, n, n+2*ng, MPI_DOUBLE, &interior);
MPI_Type_commit(&interior);
MPI_Send(startPoint, 1, interior, dest, tag, MPI_COMM_WORLD);
```
Type Map Example

- Start with `oldtype` for which
  Type Map = `{(double, 0), (char, 8)}

- What is Type Map of `newtype` if defined as below?
  `MPI_Type_vector(2,3,4,oldtype,&newtype)`

Ans:

```
{{(double, 0), (char, 8)}, {(double,16),(char,24) }, {(double,32),(char,40) },
{(double,64),(char,72), {(double,80),(char,88) }, {(double,96),(char,104)}}
```
Exercise: MPI_Type_vector

- Express
  
  MPI_Type_contiguous(count, old, &new);

  ...as a call to MPI_Type_vector

  ```c
  MPI_Type_vector(int count, int blocklength, int stride, MPI_Datatype oldtype, MPI_Datatype *newtype);
  ```

- Ans:
  
  ```c
  MPI_Type_vector (count, 1, 1, old, &new);
  MPI_Type_vector (1, count, count, old, &new);
  ```
Outline

- Introduction to message passing and MPI
- Point-to-Point Communication
- Collective Communication
- MPI Closing Remarks
In some MPI implementations there are more than 300 MPI functions

- Not all of them part of the MPI standard though, some vendor specific

Recall the 20/80 rule: six calls is probably what you need to implement a decent MPI code...
The PETSc Library
[The message: Use libraries if available]

- PETSc: Portable, Extensible Toolkit for Scientific Computation
  - One of the most successful libraries built on top of MPI
  - Intended for use in large-scale application projects,
  - Developed at Argonne National Lab (Barry Smith)

- PETSc provides routines for the parallel solution of systems of equations that arise from the discretization of PDEs
  - Linear systems
  - Nonlinear systems
  - Time evolution

- PETSc also provides routines for
  - Sparse matrix assembly
  - Distributed arrays
  - General scatter/gather (e.g., for unstructured grids)
Structure of PETSc

PETSc PDE Numerical Solution Utilities

- ODE Integrators
- Visualization
- Nonlinear Solvers, Unconstrained Minimization
- Interface
- Linear Solvers
- Grid Management
- Preconditioners + Krylov Methods
- Object-Oriented Matrices, Vectors, Indices
- Profiling Interface

Computation and Communication Kernels
- MPI, MPI-IO, BLAS, LAPACK
# PETSc Numerical Components

PETSc code
CUDA, OpenMP, MPI: Putting Things in Perspective
Pros, CUDA

- Many remarkable success stories when the application targeted is data parallel and with high arithmetic intensity
  - One order of magnitude speed-ups are common

- Very affordable – democratization of parallel computing
  - At a price of $10K you get half the flop rate of what an IBM BlueGene/L got you six or seven years ago

- Ubiquitous
  - Present on more than 100 million computers today support CUDA

- Good productivity tools
Cons, CUDA

- To extract last ounce of performance that makes GPU computing great you need to understand the computational model and the underlying hardware.

- Not that much device memory available – 6 GB is the most you get today.
  - Getting around it requires moving data in and out of the device, which complicates the programming job.

- Until the CPU and GPU are fully integrated, the PCI connection is impacting performance and complicating the implementation task.

- For true HPC, using CUDA in conjunction with MPI remains a challenge.
  - Ongoing projects aimed at addressing this, but still…
What Would Be Nice…

- The global memory bandwidth should increase at least as fast as the rate at which the number of scalar processors increases

- Integrate CPU & GPU so that concept of global device memory disappears

- Have the OpenACC standard succeed for seamless parallel accelerator and/or many-core programming
Pros of OpenMP

- Because it takes advantage of shared memory, the programmer does not need to worry (that much) about data placement
- Programming model is “serial-like”, thus conceptually simpler than message passing
- Compiler directives are generally simple and easy to use
- Legacy serial code does not need to be rewritten
Cons of OpenMP

- The model doesn’t scale up all that well

- In general, only moderate speedups can be achieved
  - Because OpenMP codes tend to have serial-only portions, Amdahl’s Law prohibits substantial speedups

- Amdahl’s Law:
  \( s \) = Fraction of serial execution time that cannot be parallelized
  \( N \) = Number of processors

\[
\text{Execution speedup: } = \frac{1}{s + \frac{1-s}{N}}
\]

- If you have big loops that dominate execution time, these are ideal targets for OpenMP
Pros of MPI

- Good vendor support for the standard
  - It was great that the community converged upon a standard (something that can’t be said about GPU computing)

- Proven parallel computing solution, demonstrated to scale up to hundreds of thousands of cores

- Can be deployed both for distributed as well as shared memory architectures

- Today it is synonym with High Performance Computing
  - Provided a clear and relatively straightforward framework for reaching Petaflops grade computing
Cons of MPI

- The interconnect is Achilles' heel. Top bandwidths today are comparable to what you get over PCI-Express
  - Latency typically worse though

- Like CUDA, works well only for applications where you don’t have to communicate all that much (high arithmetic intensity)
General Remarks on Parallel Computing

- Parallel Computing is and will be relevant at least for this decade

- Nonetheless, it continues to be challenging

  - Switching your thinking about getting a job done from sequential to parallel mode takes some time but it’s a skill that is eventually acquired
    - Parallel Programming more difficult than programming for Sequential Computing

  - Productivity tools (debuggers, profilers, build solutions) more challenging to master

  - Need to understand the problem that you solve, the pros/cons of the parallel programming models available, and of the hardware on which your code will run
Skills I hope You Picked Up in ME759

- I think of these as items that you can add to your resume:
  - Basic understanding of hardware for parallel computing
  - Basic understanding of parallel execution models: SIMD, MIMD, etc.
  - CUDA programming
  - OpenMP Programming
  - MPI Programming
  - [ Build management: Cmake ]
  - Debugging: gdb, cuda-gdb, memcheck, cuda-memcheck
  - Profiling: nvvp
ME759: Most Important Two Things

- Don’t move data around
  - Costly in terms of time and energy.

- Hone your “computational thinking” skills
